- 6. Photographic guide to our salamanders.
- 7. Photographic guide to regional stream fish.
- 8. Table of aquatic results from Hawthorne Valley stream studies.

Appendix 1. Photographic guide to common grasses and legumes of our pastures.

HABIT:

- Medium size (to 100 cm)
- Perennial
- Bunchgrass
- Leaves ribbed and rough above, glossy below
- Leaf margins +/- smooth
- Inflorescence is a long spike with spikelets facing central axis with their <u>narrow</u> side (compare with quackgrass)

Spikelets awned

COLLAR REGION:

- Ligule very short (<1mm)
- Prominent clasping auricles (similar to quackgrass)
- Sheath open

GENERAL OBSERVATIONS:

- ·Seems to occur in most pastures
- Starts flowering in early June
- Without flowers, easily confused with tall fescue
- Supposedly produces excellent quality forage

Italian Ryegrass (Lolium perenne var. aristatum)

- Small to medium size (30-100cm)
- Perennial
- Sod-former, spreads with rhizomes
- ·Leaves short and narrow
- Characteristic prowshaped leaf tip
- ·No hairs

- •Ligule +/- 2mm
- ·No auricles
- Open sheath, margins might touch up to collar

Kentucky Bluegrass

(Poa pratensis)

- The most common pasture grass, also the most common lawn grass; it survives repeated grazing or cutting because its growing point remains low to the ground
- One of the first to grow in spring, starts to flower in May

Orchard Grass (Dactylis glomerata)

- ·Medium size (60-120 cm)
- Light green
- Perennial
- Bunchgrass
- Young shoots flattened
- ·No hairs
- Leaves +/- soft on both surfaces
- Margins not cutting

COLLAR REGION:

- Ligule 5-7 mm (similar to that of reed canary grass and timothy)
- · No auricles
- Sheath open, but margins touching

- One of the most common pasture grasses; the moderately low growth habit allows it to withstand grazing
- One of the first to grow in spring, starts flowering in May
- The cows like to eat the young plants, but avoid the inflorescence

- Medium sized (50-100 cm)
- Perennial
- Creeping rhizomes
- Leaves sparsely hairy
- Inflorescence is a long spike with spikelets facing the central axis with their broad side (compare with ryegrass)

- Ligule very short [<1 mm]
- Prominent clasping auricles (similar to those of ryegrass)
- Sheaths open
- Lower sheaths may have short hairs

Quackgrass

(Elytrigia repens syn. Agropyron repens)

- Occurs here and there in the pastures
- Starts to flower in early June

- •Tall (60-150 cm)
- Bluish green
- Perennial
- Spreads slowly with short, thick rhizomes
- ·Leaves without hairs
- Leaf margins rough

COLLAR REGION:

- Ligule 3-6 mm (similar to those of orchard grass and timothy)
- Broad collar
- Sheath open, but margins tightly overlapping up to collar
- Ligule membrane continues down along margins of sheath

Reed Canary Grass

(Phalaris arundinacea)

- Occurs in wet areas in the pastures and also grows in and along the creek
- Starts growing early in spring but 1st flowers seen only in early June
- Supposedly needs to be kept grazed down to less than 12", otherwise becomes unpalatable to cows

- Medium size (50-100 cm)
- Perennial
- Sod-former spreading with short rhizomes
- No hairs
- Leaves +/- smooth on both surfaces

COLLAR REGION:

- •Ligule 1.5-2 mm
- ·No auricles
- Collar wide and sometimes folded
- Characteristic closed sheath(!)

Smooth Brome Grass

(Bromus inermis)

- ·Occurs here and there in most pastures
- Its leaves supposedly provide excellent early spring grazing
- Starts flowering in early June and can be seen mostly along the edges of pastures (and roads)

- Small to medium size (30-60 cm)
- Grows in small clumps
- Perennial
- Leaves very short (!)

COLLAR REGION:

- •Ligule +/- 2mm
- •No auricles, but characteristic fringe of hairs at the margins of the leaf base (!)
- Open sheath

GENERAL OBSERVATIONS:

- Spread throughout most of our pastures
- One of the first grasses to grow and flower in spring (first flowers seen in late April)
- Supposedly has little nutritional value for the cows

Sweet Vernal Grass

(Anthoxanthum odoratum)

- Medium size (50-100 cm)
- Perennial
- Bunchgrass with short rhizomes and stolons
- Stems whitish and swollen (bulb-like) at the base

COLLAR REGION:

- Ligule 2-4 mm (resembles that of orchardgrass)
- ·No auricles
- ·Sheaths open

- Seems to be quite common in some pastures
- Starts flowering in early June
- Supposedly the best all-around pasture grass

- Medium size (50-120 cm)
- Perennial
- Bunchgrass with short rhizomes, can form dense sod
- Leaves ribbed and rough above, glossy below
- Leaf margins rough

COLLAR REGION:

- Ligule very short [<1 mm]
- Auricles blunt and lobe-like with or without hairs (sometimes similar to those of ryegrass and quackgrass)
- Sheaths open

Tall Fescue

(Festuca elatior)

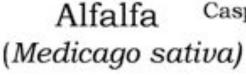

- Occurs here and there in the pastures
- Supposedly tolerates continued close grazing

- · Erect and bushy (1-3 ft tall)
- Flowers purple, in short raceme
- Trifoliate (each leaf is composed of three leaflets) {1}
- Leaflets elliptical to obovate, margin toothed mostly in upper half {2}, small projecting tip {3}
- Terminal leaflet stalked, often turning upward {4}
- Stipules lance-shaped with a long, narrow tip {5}

! Without flowers, it is similar to other trifoliate legumes with stalked terminal leaflets. However, black medick does not grow as tall and tends to have more roundish leaflets; sweet clovers have entirely toothed margins.

*Alfalfa has been seeded into some of pastures and hayfields. Native of the Caspian area.

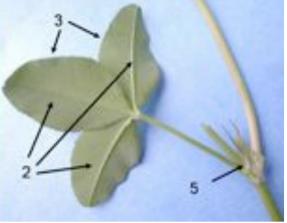

Alsike Clover (Trifolium hybridum)

- Ascending, glabrous (not hairy)
- Pink to white flowers in stalked flower heads {1}
- Trifoliate (each leaf is composed of three leaflets) {2}
- Leaflets oval (tend to be broadest near the middle), with pronounced serration {3}, never with a lightcolored V-shaped line or triangular patch {4}
- Stipules light colored with a broad base attached to the stem and a long narrow free tip {5}

! Without flowers, the leaves might be confused with those of red clover, which has a similar leaflet size and shape, but is pubescent and not as strongly serrate, or with those of white clover, which has smaller, more rounded leaflets that are not as strongly serrate.

*Found on almost all our pastures and hayfields. Native of Eurasia.

- · Prostrate to suberect
- Big (1.5 cm) yellow flowers in few-flowered umbells
- Trifoliate (each leaf is composed of three leaflets), but the stipules have the size and shape of leaflets {1}, so that the leaf appears to have five leaflets
- Leaflets elliptic to oblanceolate, margins entire (no serration)

! Not easily confused with any other clover, because none of our other clovers has stipules of the size and shape of its leaflets, and none has such large yellow flowers.

* It grows in almost every meadow and pasture. Native of Europe.

Birdsfoot Trefoil (Lotus corniculatus)

- Sprawling
- Flowers yellow, in tiny, round, long-stalked inflorescences
- Trifoliate (each leaf is composed of three leaflets) {1}
- Leaflets obovate, margin toothed at least in upper half {2}, small projecting tip {3}
- Terminal leaflet stalked, often turning upward {4}
- Stipules lance-shaped (5)

! Quite similar to hop clovers, the most common of which, palmate hop clover, does not have stalked terminal leaflets and grows taller. Also similar to alfalfa and the sweet clovers, which grow much taller and tend to have more elliptical leaflets.

*Occurs in small amounts in almost all pastures and

hayfields. Native of Eurasia.

Black Medick (Medicago lupulina)

- Trailing or climbing with tendrils {1}
- Flowers purple, in many-flowered, onesided racemes
- Leaflets 5-11 pairs

! Without flowers, it is similar to crown vetch, but can be distinguished by its tendrils. The other common vetch, four-seeded vetch, has shorter leaves (2-5 pairs) and tiny flowers born singly or in pairs.

* Sometimes found along the edges of pastures and hayfields. It is a native of Eurasia and possibly of northeastern North America.

Bird- or Cow Vetch (Vicia cracca)

- Loosely ascending
- Flowers pinkish, in stalked umbels
- Leaflets 11-25
- No tendrils

! Without flowers similar to Cow-Vetch, but lacking tendrils.

* Found along the margins of most pastures and hayfields, very common along roadsides. It is a native of the Mediterranean region.

Crown-Vetch (Coronilla varia)

- Trailing or climbing with tendrils {1}
- Flowers light purple to white, born singly or in pairs
- Leaflets 2-5 pairs
- Seedpods with 4 seeds
- ! Much more delicate than the other vetches.
- * Easily overlooked, but found in most pastures and hayfields. Native of Eurasia.

Four-Seeded Vetch (Vicia tetrasperma)

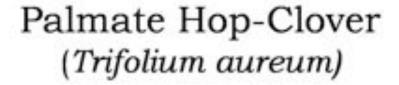

- Ascending, much branched, stems appressed-hairy
- Flowers yellow, in short-cylindrical, stalked inflorescences
- Trifoliate (each leaf is composed of three leaflets) {1}
- · Leaflets oval and serrate
- Stipules {2} tend to be approx. as long as the leaf stalk {3}

! Might be confused with black medick, which has stalked terminal leaflets, a much smaller flower head and is generally a smaller plant. Pinnate hop-clover is smaller, has a stalked terminal leaflet, and leaf stalks that are longer than the stipules.

* Found interspersed in many meadows, mostly along the edges. Native of Eurasia.

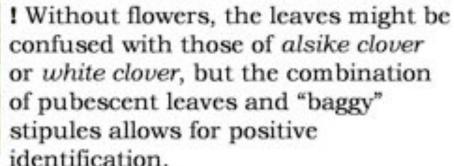

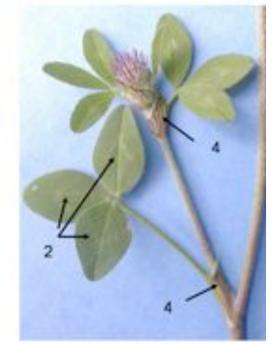

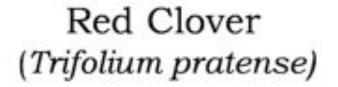

- Ascending, pubescent (hairy)
- Red to magenta or pinkish flowers in stalkless flower heads (sitting on top of a pair of leaves) {1}
- Trifoliate (each leaf is composed of three leaflets) {2}
- Leaflets oval (tend to be broadest near the middle), very shallowly serrate, sometimes marked with a light-colored triangular patch {3}
- Stipules "baggy", light colored with dark veins, attached to stem for three-quarters of their length, with short, narrow free tip {4}

* Common in all pastures and hayfields. Native of Europe.

White Clover

- Creeping, entire plant glabrous (not a bit hairy)
- Flower heads and leaves emerging on individual stalks {1} which branch off the main stem {2} creeping along the ground
- Flowers white to pink, in round, longstalked inflorescences
- Trifoliate (each leaf is composed of three leaflets) {3}
- Leaflets broad elliptic to obovate, somewhat serrate, sometimes marked with a light-colored V-shaped line {4}

! Without flowers, the leaves might be confused with those of alsike clover, which are also glabrous, but tend to be more oval with pronounced serration of the margins, or with those of red clover, which have a pubescent (hairy) underside. The light-colored leaf markings of red clover leaves tend to be more in the shape of a triangle

* One of the most common pasture plants. Native of Europe.

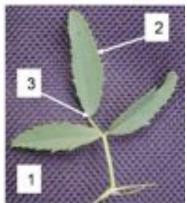

- · Erect, much branched, 3-8 ft tall
- Flowers white, in many-flowered racemes
- Trifoliate (each leaf is composed of three leaflets) {1}
- Leaflets quite narrow and serrate {2}
- Terminal leaflet stalked (3)

! Without flower, this plant is hard to distinguish from yellow sweet clover. Might also be confused with alfalfa, which has a similar leaflet shape and a stalked terminal leaflet, but the serration on alfalfa leaflets is limited to the upper half.

* Typically a plant of road-sides, but sometimes found along the edges of pastures and hayfields. Native of Eurasia.

White Sweet Clover (Meliotus alba)

- Erect, much branched, 3-8 ft tall
- Flowers yellow, in many-flowered racemes
- Trifoliate (each leaf is composed of three leaflets) {1}
- Leaflets quite narrow and serrate {2}
- Terminal leaflet stalked {3}

! Without flowers, this plant is hard to distinguish from white sweet clover. Might also be confused with alfalfa, which has a similar leaflet shape and a stalked terminal leaflet, but the serration on alfalfa leaflets is limited to the upper half.

* Typically a plant of road-sides, but sometimes found along the edges of pastures and hayfields. Native of Eurasia.

Yellow Sweet Clover (Meliotus officinalis)

Appendix 2. List of wild plants documented on Columbia County farms.

¹¹ Plant identifications and names are mostly based on Gleason & Cronquist (1991); "Manual of Vascular Plants of Northeastern United States and Adjacent Canada, 2nd. ed."; we also consulted McVaugh (1968); "Flora of the Columbia County Area, New York", and several illustrated field guides

²⁾ Growth forms: heherbaceous, lewbody liana, sestrub, tetree, vevine

Native plants: n=considered native to our region; n(p)=native to our region but also native to the midwestern taligrass pariries (according to "The Taligrass Restoration Handbook for Prairies, Savannas and Woodlands" (1997) edited by Stephen Packard and Cornelia F. Mutel); ? native and introduced populations or subspecies of a species occur in our region.

⁴⁾ Conservation interest: marked in this column are plants of conservation concern that are legally protected (as posted on http://www.plants.usda.gov) or considered rare or scarce or of uncertain status in the Hudson Valley by Hudsonia (Kiviat and Stevens 2001); e=endangered in NYS, v=exploitably vulnerable in NYS; o=legally protected in other states; r=rare in Hudson Valley, s=scarce in Hudson Valley, ?=uncertain status in Hudson Valley; in addition.

⁽i) Invasive plants: plants marked in this column are considered invasive according to the Invasive Plants Atlas of New England (http://invasives.eeb.uconn.edu/pane/

As described in the methods section, inventory methods were not standardized accross the farms. Therefore, the information about plant occurrences on the farms presented in this table is not valid for between-farm comparisons.

Appendix 5. Photographic guide to our frogs.

American Toad

(Bufo americanus)

Toads in general can be told from the frogs of our area by their warts. They also tend to be browner (although the Wood Frog is brownish too) and drier-skinned. They are often found in drier areas than most frogs, although, as the pictures show, they do breed in ponds.

We have two other possible toad species in our area, the Spadefoot and Fowler's Toads. The rare Spadefoot (which we have not seen in the County), with its vertical pupil, distinct coloration and small parotoid gland, should be fairly obvious. The Fowler's Toad is more similar and requires closer inspection (see Fowler Toad page in this Appendix).

Fowler's Toad

(Bufo fowleri)

We have found Fowler's
Toad in dry woods and
grasslands near wetlands
(but not yet on any
working farms). We
include it here because of
its presence in our area
and its similarity to the
American Toad.

This is a southern species which reaches its northern limits in our region, extending into New York mainly along the Hudson River Valley.

Belly coloration and the number of warts per dark patch are said to be distinguishing characteristics.

Green Frog

(Rana clamitans)

The Green Frog is our most common frog – learn to identify it and you will be able to name most frogs you see!

Green Frogs have variable coloration that is due in part to age, condition and gender. The top photo is of a mating male - his throat is yellow, the rest of him green, and his ear drum is much larger than his eye. The female at left is younger, but the pair below provides a good comparison, male on right, female on left. The individual below shows the degree of splotching that some green frogs have. Importantly, their "splotches" are not surrounded by light margins as in Pickerel or Leopard Frogs.

Pickerel Frog

(Rana palustris)

Unlike any of the other frogs that we have commonly seen in our area, the Pickerel Frog has very distinct blotches surrounded by dark borders. The lateral folds of skin are lighter than the rest of the body, making for quite a trim-looking beast.

We have found this species mainly along creeks, although occasionally also around ponds. In other words, in many of the places we found the more common green frog.

The regionally rare
Leopard Frog also has
distinct blotches, but that
species' blotches are not
square nor so neatly
aligned; it also doesn't
have yellow underpants
and its blotches have light
margins.

Bullfrog

(Rana catesbeiana)

This is our largest frog; the one pictured on top was roughly 10 inches long. Of course, they need to grow to that size and, when young, can be confused with the smaller and often co-occurring Green Frog. The key characteristic is that the fold of skin that begins behind each eye wraps around the ear drum. rather than continuing down the back as in the Green Frog.

Bullfrogs were scattered in our survey area. We found them mainly by permanent ponds. They are said to be voracious predators, and their presence can exclude some other amphibian species.

Males have large eardrums which abut the eyes; the individuals pictured here all appear to be females.

Wood Frog

(Rana sylvatica)

This is our flagship vernal pool frog. They gather en masse in early spring for a brief mating period, leaving the distinctive clumps of eggs seen below.

Their dark mask is characteristic, although given variation in the brownish hue of the body, it is sometimes more or less conspicuous.

Appendix 6. Photographic guide to our salamanders.

Redback Salamander

Plethodon cinereus

Redback salamanders are our most common woodland salamanders. Find a moist, healthy forest in our area, start turning over rocks and logs, and you are likely to find them. This species lays its eggs on land and, as the lower right photo shows, the young look like miniatures of the adults.

This is a slim salamander. It usually has a reddish back. There is, however, a 'leadback' coloration which is greyer. Four-toed Salamanders, a possible source of confusion, are rarer, browner, have a bright white belly with dark dots, and a squarer nose. We have not yet found Four-toed Salamanders on any farms.

Northern Dusky Salamander Desmognathus fuscus

These salamanders are not as aquatic as the Two-lined, nor as terrestrial as the Redback. They are commonly found along the banks of streams or in seeps.

As young (upper two pictures), they have vague reddish dots. As adults, they are dark bodied, not as stocky as mole salamanders, but have heavy hind legs. A light line extending from the back of the eye to the back of the jaw is distinctive of this genus. The Mountain Dusky is similar, but said to have a herringbone pattern on its back; we haven't found it (so far as we know!).

As adults, this species seems unmistakable. It is a large (reportedly up to 10 inches long), black salamander with bright yellow polka dots. The gilled young develop for 2-3 months in the pools, finally metamorphosing into the dull semi-terrestrial version seen in the upper right hand corner.

Outside of their pond lives, they spend the year lurking in or near their burrows (hence the Ambystoma salamanders are called "mole salamanders").

Often the most obvious evidence of this species are its gelatinous egg clusters or small "spermatophores". Spermatophores are the tiny, spermtopped structures males leave on pool bottoms in Spring; they look like single curds of cottage cheese.

This is a rarer vernal pool salamander. While it seems to frequent the same general haunts as Spotted Salamanders, it seems to be a more strictly woodland sort. This species apparently interbreeds with the Blue-spotted Salamander in some areas and forms an array of hybrids.

Jefferson Salamanders are greyish-black with a lighter, sometimes bluish speckling, especially along the sides. They tend to be slightly smaller than Spotted Salamanders but are similarly stocky. They are reported to spend their adult, non-breeding period in upland tunnels, and hence are also considered "mole" salamanders.

These are slim salamanders with long tails. Their usual coloration is goldentan with two black lines starting at the eye and running down each side. Occasionally, they apparently show up in red morphs. We were told by experts that the bright red salamander shown above right is also a Twolined.

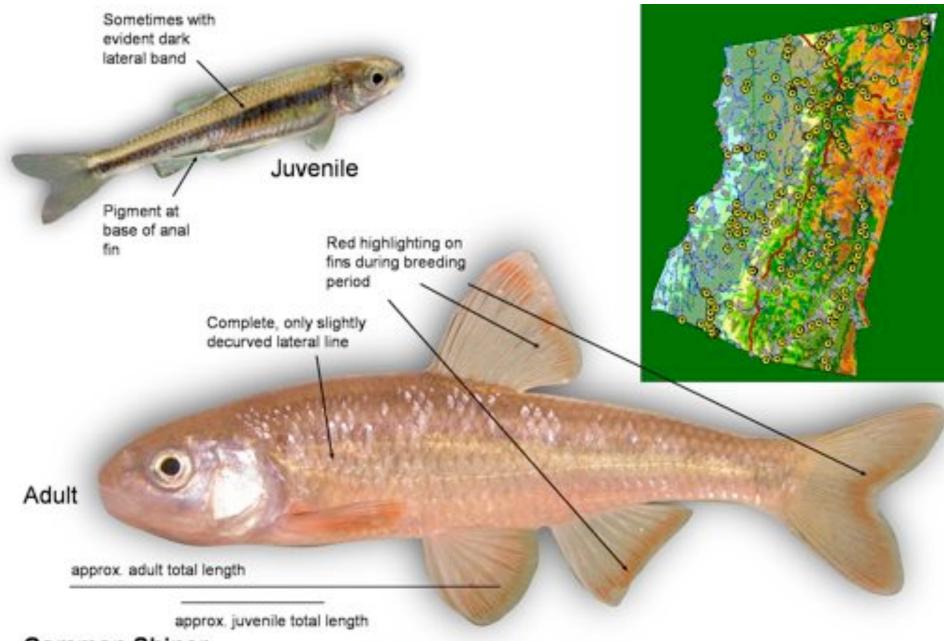

Larvae were often found under rocks (as the photo of larvae awaiting rerelease, upper left, shows). The adults, while less abundant, were commonly found on or near shore. When released in shallow water, larvae head for the bottom, while adults head towards shore.

Red-spotted newts abound in our area. They are frequently found in permanent ponds, where their toxic skin appears to protect them from at least some predation. They have an interesting life-cycle: born in the pond, the young larvae develop until they are able to come ashore. Once ashore, they wander about for a year or two in the bright orange coloration shown at top. This is the Red Eft stage. They return to the ponds as adults, developing a darker coloration and a wide, propulsive tail.

There is no mistaking the Red Eft stage – its colors shout out for attention (apparently not a bad idea if you are poisonous). The adult newt is less conspicuous, but its red dots are usually apparent, and its slim head and broad tail are distinctive.

Appendix 7. Photographic guide to regional stream fish. This Shiner eats mostly zooplankton, supplemented with algae and insects. Tends to have a more silvery or golden coloration Sharply decurved lateral line Long anal fin Golden Shiner Notemigonus crysoleucus approx. total length

Common Shiner
Notropis cornutus

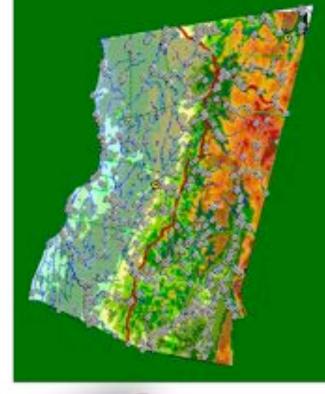

These fish eat both plant and animal (mainly insect) material, often scavenging near the surface.

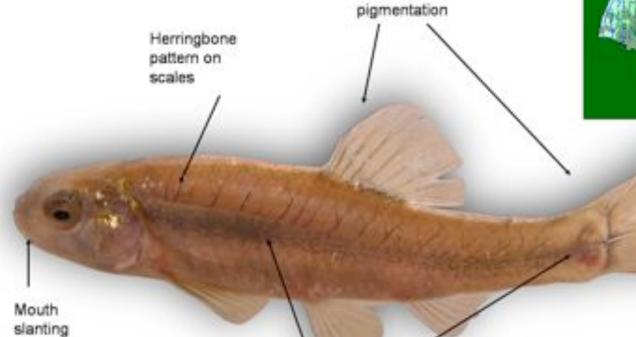

Bumps on head of breeding fathead male

This species feeds mainly on algae, zooplankton, insects and plants found on the bottom.

At least hints of

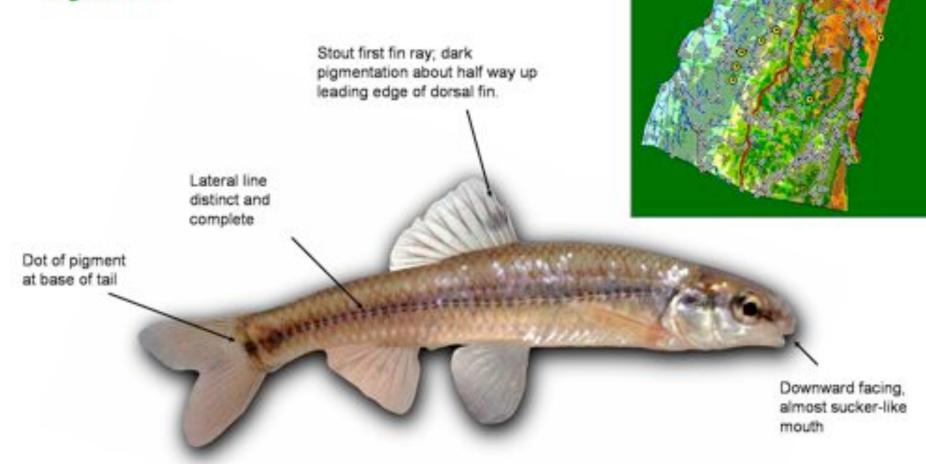

Fathead Minnow Pimephales promelas

Body, especially base of tail, stout

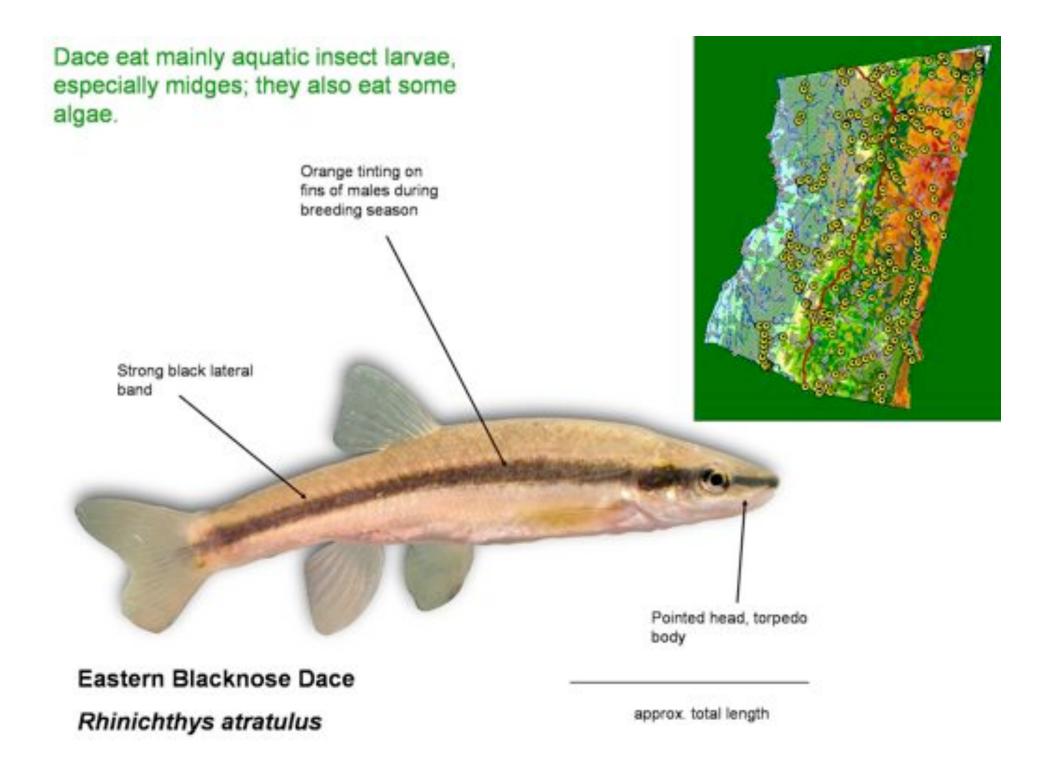

approx. total length

This Shiner eats mainly on the bottom, where it consumes zooplankton, algae and other small organisms.

Bluntnose Shiner
Pimephales notatus

approx. total length

Creek Chub are omnivorous. They eat plants, algae, insects, plankton and small vertebrates. Strong lateral black band Distinct pigment spot at base of dorsal fin Creek Chub We usually see specimens of this species that range between these lengths Semotilus atromaculatus

Fallfish are omnivorous; they eat plants, algae, insects, plankton and small vertebrates.

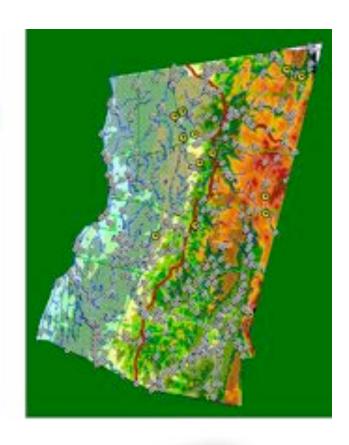

> Definitive character is hard to see (flap of tissue on lips); this is a long, relatively slim minnow. Not as blunt as Common Shiners of its size; without the deeply decurved lateral line of the Golden Shiner.

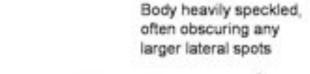

A somewhat older longnose, note small scales and obscure coloring

This fish collects zooplankton and small insects from the bottom.

Sucker mouth, lips flaring backwards

Longnose Sucker
Catostomus catostomus

Scales small and difficult to distinguish

This is approx. length of most specimens we catch; but the species can grow much longer.

Relatively lightly pigmented body with large scales; large lateral spots sometimes quite apparent

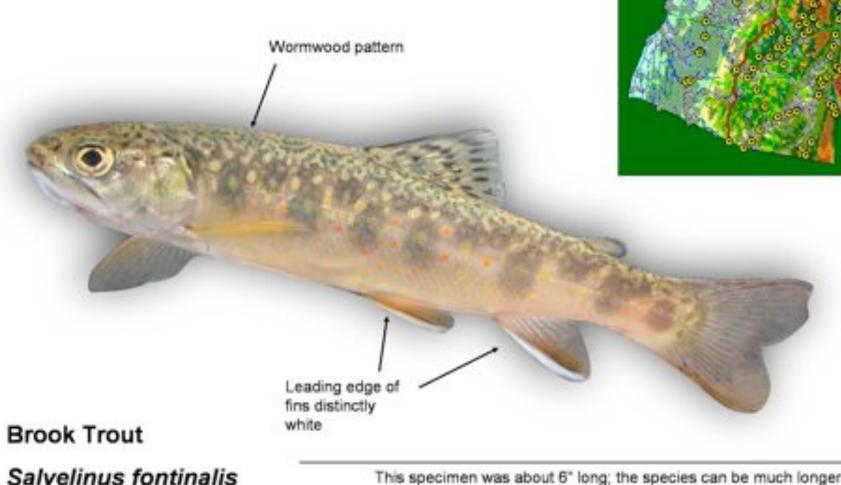

White Sucker

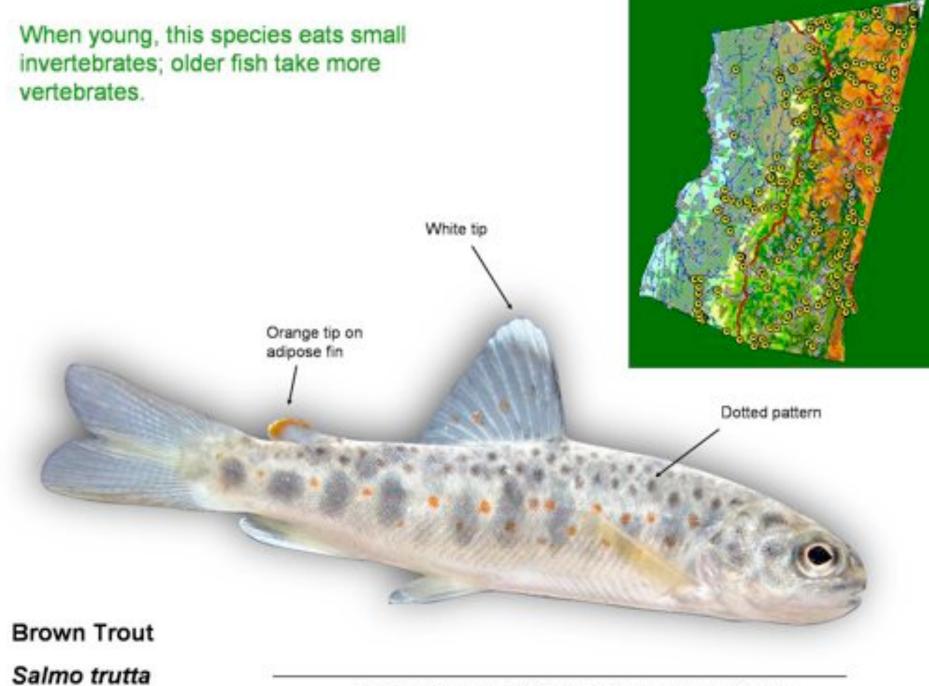

Catostomus commersoni

Downward-facing, sucker mouth

This is approx. length of most specimens we catch; but fish can get much longer Brook Trout mainly eat insects and invertebrates, many of which are aquatic but it also takes terrestrial organisms that accidentally fall in the water. Larger individuals may eat small vertebrates.

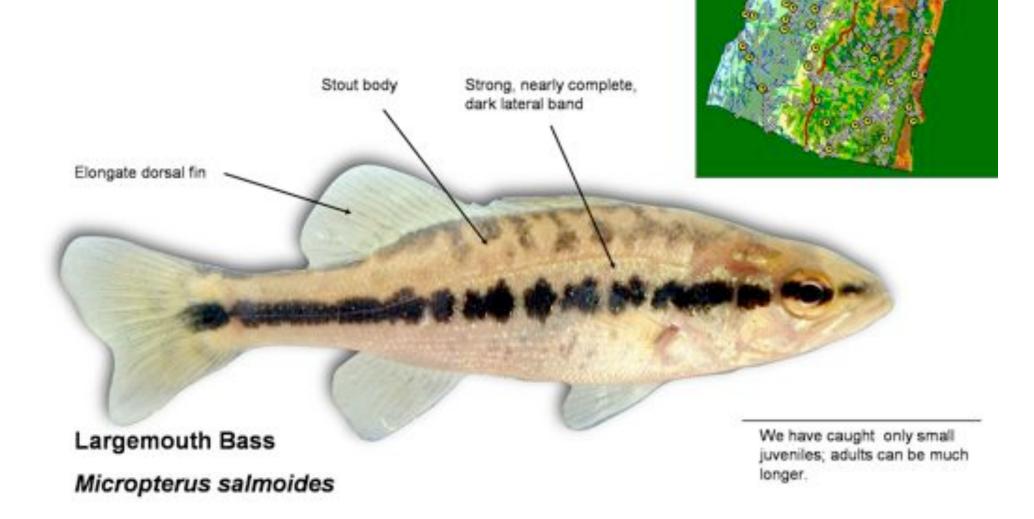

This specimen was about 6" long; the species can be much longer.

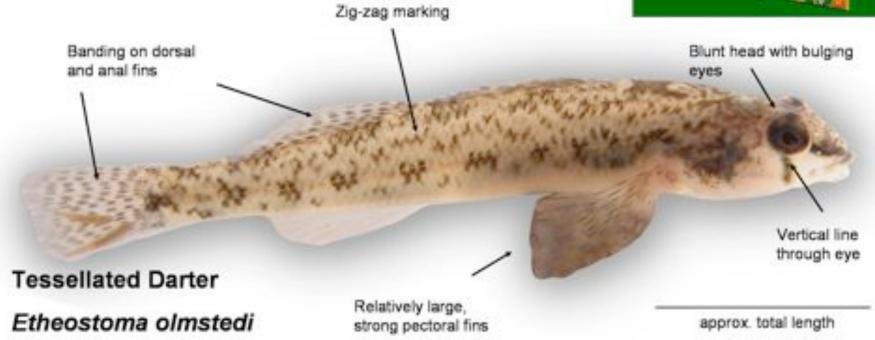

This specimen was about 6"; the species can be much longer.

Largemouth Bass eat plankton and invertebrates when young; they grow more carnivorous with age.

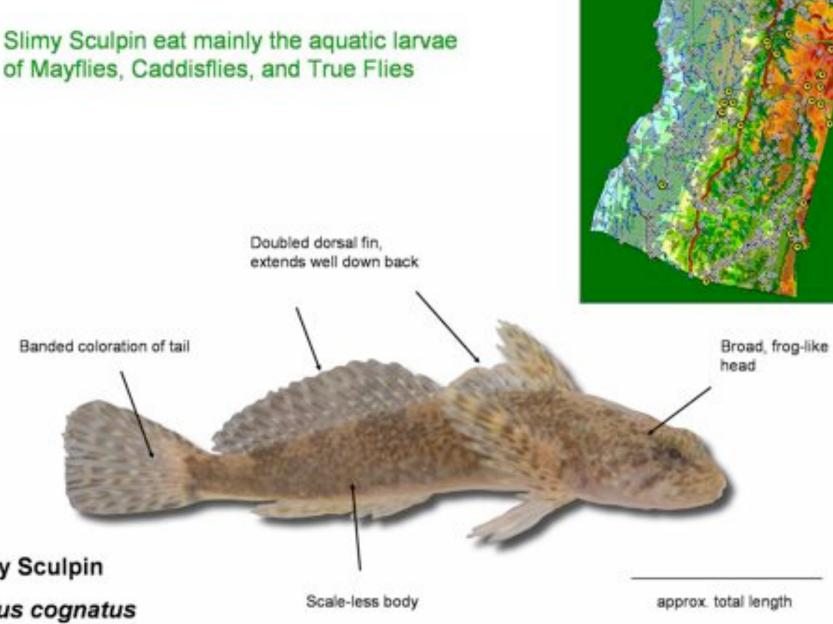

This Darter eats mainly small crustaceans and other invertebrates.

Slimy Sculpin

Cottus cognatus
